Per session, from the upper-quartile GPS speed:
>= 2.5 m/s vehicle (every frame, min hits 6); otherwise
walking or default (every 3rd frame, min hits 3).
Max age is 15 source frames in both modes.
Next analysed frame with detections d_1 ... d_k
For each live track: predicted box = last box moved by its
velocity x elapsed source frames (box size unchanged)
Pairs (track, detection) with IoU(predicted box, detection) >= 0.2;
greedy one-to-one assignment, highest IoU first
next frame
Matched:
append detection
to the track
Unmatched
detection:
start a new track
Unmatched track
older than 15
source frames: ends
End of video:
all live tracks
end (flush)
Ended track: confirmed if hits >= min hits,
otherwise counted as rejected
Confirmed track = one observation:
best-confidence frame, last box,
last time seen
